Author: Aman Shukla (491001)

Constellation Cetus with redshift not greater than 0.375 microns.

Content: In the vicinity of larger background these so called Einstein Rings are the adjoining vacuum started from the galaxy's core and reaching upto the edge of Abell 370. The so called influx visible here refracting light from the farther universe is not cause of the huge mass but cause of the Inertial tilted pull (/) starting from the centre of the galaxies shown here and merging very far away from them. Stating empty space can be flowed to max.

Biggest Questions that have surfaced after witnessing these facts:

- How much interaction can lead to direct shift at the far away point and does it happen immediately?
- What connects two points in vacuum? Is it centrifugal dense point causing all the havoc or is it space following the parameters set by the galactic trajectory?

These observations also bring the idea of Universality, which shows that once entropy is changed it remains unchanged. The increase in shift from nominal to max, represents the increasing vacuum holding of the galaxy and vice versa. The vacuum symmetry once started by visible matter can clung beyond on both sides.

These observation also proves the fact that the Black Holes are hugely compressed visible matter which are found only at the centre of galaxies.

Warning! Label has been put under for organizations.
